# Written Assignment 2

## Submission Instructions:

- Individual submissions only
- Submission must be in PDF format, and should be uploaded via Moodle
- All 3 questions are mandatory
- Submission deadline is the **18<sup>th</sup> of April, 2021 (23:55 Israel Standard Time)**

## Question 1:

Choose 5 out of 7 sections, 5 extra points will be given if all 7 sections are solved correctly:

- What is the implicit representation of the 2D plane that is tangent to the sphere  $S$  at the point (4,3,4):  
$$S: (x - 1)^2 + (y - 2)^2 + z^2 - 26 = 0$$
- What is the implicit representation of the 2D plane that passes through the point (6,1,0) and is parallel to a line that lies on the  $yz$ -plane? How many possible solutions exists?
- Let  $f_1(x, y, z)$  and  $f_2(x, y, z)$  be implicit representation of two spheres. Also assume that the spheres intersect on more than two points. Explain in detail what does the following surface represent:

$$\begin{aligned} S = \{(x, y, z) | f_1(x, y, z) = 0 \text{ and } f_2(x, y, z) > 0\} \\ \cup \{(x, y, z) | f_2(x, y, z) = 0 \text{ and } f_1(x, y, z) > 0\} \end{aligned}$$

In otherwards,  $S$  is the set of points  $(x, y, z)$  that satisfy either of the following:

- $f_1(x, y, z) = 0$  and  $f_2(x, y, z) > 0$
- $f_2(x, y, z) = 0$  and  $f_1(x, y, z) > 0$

Is this surface closed? If not, how would you change  $S$  so that the surface is closed?

- The point  $p = (a, 7, b)$  lies on the plane  $2x + y + z + 1 = 0$ . Determine all possible values of value of  $a$  and  $b$ . What does the set of all possible points  $p = (a, 7, b)$  represent?
- A line  $L$  lies on the plane:  $x + y + z + 1 = 0$ , the line direction is  $(a, 1, 0)$  for some value  $a \in \mathbb{R}$ :
  - Can you determine the line equation from the given details above? How many possible lines exist?
  - If the line also passes through the point  $(1, -1, -1)$ , can you determine the line equation? How many lines exist?
- A 3D sphere is centered at the origin, and a 2D plane  $\pi$  is given by the implicit equation:  
$$\pi: a \cdot x + b \cdot y + c \cdot z + d = 0$$

The intersection of the sphere and the plane  $\pi$  forms the circle given by the parametric representation:

$$\begin{aligned} x &= 0 \\ y &= \frac{3}{\sqrt{2}} \sin \theta \end{aligned}$$

Instructor: Prof. Ariel Shamir

Submission due: 18<sup>th</sup> of April 2021 (23:55 IST)

$$z = \frac{3}{\sqrt{2}} \cos \theta$$

Where  $\theta \in [0^\circ, 360^\circ]$ . Calculate the radius of the sphere and the plane's equation  $\pi$ .

- g) Find the intersection of the 2D line and a plane below using only their parametric representation:

$$l: (3,2,0) + (-1,1,5)t$$
$$\pi: (0, -1, 4) + (1,1,0)t + (5,1,-2)s$$

**Question 2:**

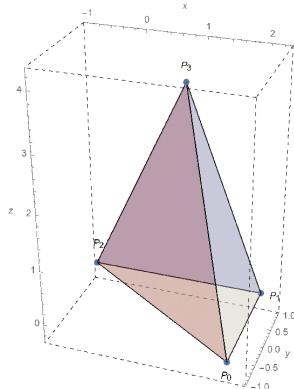

- Let  $l(t) = q + v \cdot t$  be the parametric representation of a line, where  $v$  is a **unit** norm vector and  $q$  is a point on the line. Find the projection of a point  $p = (x, y, z)$  on the line  $l(t)$ .
- Let  $p_1$  and  $p_2$  be two points and let  $p'_1$  and  $p'_2$  be their projection on the line  $l$ , respectively. Prove that  $\|p'_1 - p'_2\|_2 \leq \|p_1 - p_2\|_2$
- Can the argument in section (b) be extended to 2D planes? Meaning, let  $p_1$  and  $p_2$  be two points and let  $p'_1$  and  $p'_2$  be their projections on the 2D plane  $\pi$ . Prove or disprove that  $\|p'_1 - p'_2\|_2 \leq \|p_1 - p_2\|_2$  for any two points  $p_1, p_2$ . You may assume the plane  $\pi$  is given by the unit normal  $n$  and a point  $q$ .

**Question 3:**

A tetrahedral is given by the points:

$$P_0 = (2, -1, 0), P_1 = (2, 1, 0), P_2 = (-1, 1, 0), P_3 = (1, 0, 4)$$

See figure below as a reference:

- Determine the **unit** normal (facing outside) of the triangles faces of the tetrahedral.
- Calculate the implicit equation of the planes that contain the tetrahedral's faces
- Explain in-detail how to determine if a point  $p = (x, y, z)$  is **inside** the tetrahedral.
- A point  $p = (x, y, z)$  lies inside the tetrahedral. Determine the distance of the point  $p = (x, y, z)$  from the tetrahedral surface.

# Computer Graphics - HW 2

Prague Oshri  
204868046

## Question 1:

- a) What is the implicit representation of the 2D plane that is tangent to the sphere S at the point  $(4, 3, 4)$

$$S: (x-1)^2 + (y-2)^2 + z^2 - 26 = 0$$

$\Rightarrow$  the center of the sphere is  $(1, 2, 0)$

let  $\vec{n}$  be the vector from the center to the point  $p_0 = (4, 3, 4)$

$$\Rightarrow \vec{n} = (4, 3, 4) - (1, 2, 0) = (4-1, 3-2, 4-0) = (3, 1, 4)$$

since the plane tangent to the sphere  $\vec{n}$  is vertical to it.

$$\text{let } p = (x, y, z)$$

$$\Rightarrow \vec{n} (p - p_0) = 0$$

$$\Rightarrow (3, 1, 4) (x-4, y-3, z-4) = 0$$

$$3(x-4) + 1(y-3) + 4(z-4) = 0$$

$$3x - 12 + y - 3 + 4z - 16 = 0$$

$$3x + y + 4z - 31 = 0$$

- b) What is the implicit representation of the 2D plane that passes through the point  $(6, 1, 0)$  and is parallel to a line that lies on the  $yz$ -plane?

How many possible solutions exists?

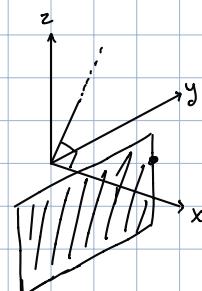

- a plane that parallel to a line lies on the  $yz$ -plane

means the plane also parallel to the plane  $yz \Rightarrow$

the equation is  $x = a$ . However we know the plane

passes through the point  $(6, 1, 0) \Rightarrow x = 6$  is the implicit representation of the plane.

Only one solution exists since any other  $x = a \neq 6$  won't pass through  $(6, 1, 0)$

c) let  $f_1(x,y,z)$  and  $f_2(x,y,z)$  be implicit representation of two spheres. Also assume that the spheres intersect on more than two points. Explain in detail what does the following surface represent:

$$S = \{(x,y,z) \mid f_1(x,y,z) = 0 \text{ and } f_2(x,y,z) > 0\} \cup \{(x,y,z) \mid f_2(x,y,z) = 0 \text{ and } f_1(x,y,z) > 0\}$$

In other words,  $S$  is the set of points  $(x,y,z)$  that satisfy either of the following

$$a: f_1(x,y,z) = 0 \text{ and } f_2(x,y,z) > 0$$

$$b: f_2(x,y,z) = 0 \text{ and } f_1(x,y,z) > 0$$

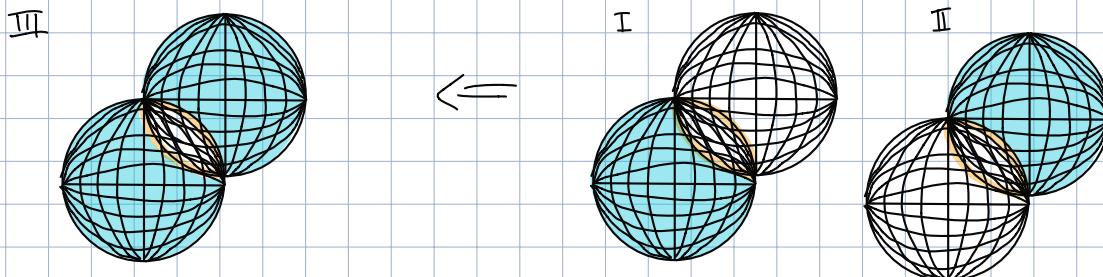

Is this surface closed? If not, how would you change  $S$  so that the surface is closed?

→ first define open sets:  $U$  is open if for any point  $p \in U$  there exist  $r > 0$

such that  $B(p,r) \subseteq U$  when  $B$  is an open ball

closed sets:  $U$  is closed set if its complement set is open

$S$  is a set of points that lies on the light blue surfaces?

$S$  contains points on the casing of  $f_1$  sphere such that not on  $f_2$  casing sphere (I) or points on the casing of  $f_2$  sphere such that not on  $f_1$  casing like (II). So the union we get any points from (III).

claim:  $S$  is open surface.

We will show that for any point  $p = (x,y,z) \in S$  there exist an open ball  $B(p, r)$  that also in  $S$ .

Let  $p = (x_p, y_p, z_p) \in S$  and without limiting generality assume  $p \in \{f_1(x,y,z) = 0 \wedge f_2(x,y,z) > 0\}$

We mark  $f_2$  as follows:  $f_2(x,y,z) = ax^2 + by^2 + cz^2 - d$ .

for  $p = (x_p, y_p, z_p) \rightarrow ax_p^2 + by_p^2 + cz_p^2 - d > 0 \rightarrow$  lets mark the value we get

as  $r \rightarrow \alpha p^2 + \beta p^2 + \gamma p^2 - d = r > r/2 > 0$ .

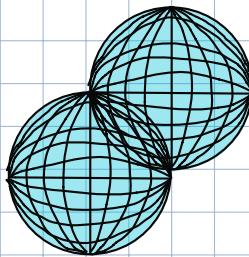

So if we take an open ball with radius of  $r/2$  on the casing of  $f_1$ , we still get an open surface of  $p$  which is  $S$ .

The same claim hold for  $p \in \{f_2(x,y,z) = 0 \text{ or } f_1(x,y,z) > 0\}$ .

→ If we want that  $S$  will be a closed surface we need to change its definition that satisfy either of the following:

a:  $f_1(x,y,z) = 0$  and  $f_2(x,y,z) \geq 0$

b:  $f_2(x,y,z) = 0$  and  $f_1(x,y,z) \geq 0$

In that way the surface will be including points of the intersection:

$f_1(x,y,z) = 0 \text{ or } f_2(x,y,z) = 0$  and for those points we don't have an open ball that still in  $S$ .

d) the point  $p = (a, f, b)$  lies on the plane  $2x + y + z + 1 = 0$ . Determine all possible values of value of  $a$  and  $b$ . What does the set of all possible points  $p = (a, f, b)$  represent?

$$\Rightarrow 2a + f + b + 1 = 0 \rightarrow \text{a line on the plane}$$

$$\Rightarrow 2a + b + 8 = 0 \rightarrow b = -2a - 8$$

$\Rightarrow$  all the points such that  $(a, f, -2a - 8)$  where  $a$  can be any real number

e) A line  $\ell$  lies on the plane:  $x+y+z+1=0$ , the line direction is  $(a, 1, 0)$  for some value  $a \in \mathbb{R}$ :

1) Can you determine the line equation from the given details above?

How many possible line exists?

→ let  $p = (x_p, y_p, z_p)$  be a point on the plane and mark the direction

$(a, 1, 0) = \vec{v}$ . so  $\ell(t) = p + t \cdot \vec{v}$ . the normal to the plane  $n = (1, 1, 1)$

is also the normal to  $\ell \Rightarrow n \cdot \vec{v} = 0 \Rightarrow 1 \cdot a + 1 \cdot 1 + 1 \cdot 0 = 0 \Rightarrow a = -1$

$\Rightarrow \ell(t) = p + t \cdot (-1, 1, 0) \Rightarrow$  there are infinity possibilities for  $p$  - a point on the plane.

2) If the line also passes through the point  $(1, -1, -1)$  can you determine the line equation? How many lines exists?

→ we know the line direction vector  $(-1, 1, 0)$  and a point the line

passes through  $\Rightarrow p = (1, -1, -1) \Rightarrow \ell: (1, -1, -1) + t(-1, 1, 0)$

only one line  $\ell$ .

f) A 3D sphere is centered at the origin, and a 2D plane  $\Pi$  is given by the implicit equation  $\Pi: ax + by + cz + d = 0$

The intersection of the sphere and the plane  $\Pi$  forms the circle given by the parametric representation :  $x=0$ ,  $y = \frac{3}{\sqrt{2}} \cdot \sin\theta$ ,  $z = \frac{3}{\sqrt{2}} \cdot \cos\theta$  where  $\theta \in [0^\circ, 360^\circ]$ .

Calculate the radius of the sphere and the plane's equation  $\Pi$ .

→ Since the center of the sphere is the origin, the radius start at the origin and end at the case of the sphere. From the circle parametric representation,

$x=0$  and we know the circle lies on the plane  $\Pi$

$\Rightarrow \Pi$  is the  $yz$ -plane, and the radius is the

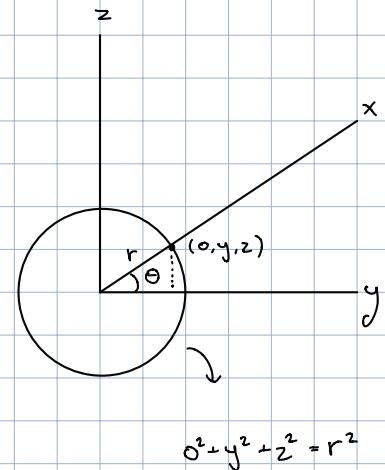

size of the vector that start at the origin  $(0,0,0)$

and end at the point  $(0, \frac{3}{\sqrt{2}} \sin\theta, \frac{3}{\sqrt{2}} \cos\theta)$

so let choose  $\theta = 90^\circ$  and get :

$$r = \| (x, y, z) \| = \| (0, \frac{3}{\sqrt{2}} \sin\theta, \frac{3}{\sqrt{2}} \cos\theta) \| = \sqrt{0^2 + (\frac{3}{\sqrt{2}} \sin 90^\circ)^2 + (\frac{3}{\sqrt{2}} \cos 90^\circ)^2}$$

$$r = \sqrt{\left(\frac{3}{\sqrt{2}}\right)^2} = \frac{3}{\sqrt{2}}$$

$$x^2 + y^2 + z^2 = r^2$$

g) find the intersection of the 2D line and a plane below using only their parametric representation:  $\ell: (3, 2, 0) + (-1, 1, 5) \cdot t$

$$\Pi: (0, -1, 4) + (1, 1, 0) t + (5, 1, -2) s$$

$$\Rightarrow \ell(t_1): (3-t_1, 2+t_1, 5t_1)$$

$$\Pi(t_1, s): (t_1+5s, -1+t_1+s, 4-2s)$$

we want to find  $t_1, t_2, s$  such that  $\ell(t_1) = \Pi(t_1, s)$

$$3-t_1 = t_1+5s \rightarrow t_2 = 3-t_1-5s$$
$$2+t_1 = -1+t_1+s \rightarrow 2+t_1 = -1+\underbrace{3-t_1-4s}_{\text{cancel } t_1} \rightarrow 2t_1 = -4s \rightarrow t_1 = -2s$$
$$5t_1 = 4-2s \rightarrow 5(-2s) = 4-2s \rightarrow -10s = 4-2s \rightarrow -8s = 4 \rightarrow s = -\frac{1}{2}$$
$$t_2 = 3-1-5 \cdot \left(-\frac{1}{2}\right) = 2 + \frac{5}{2} = 4.5$$
$$t_1 = -2 \cdot \left(-\frac{1}{2}\right) = 1$$

$$\Rightarrow \ell(t_1=1): (3-1, 2+1, 0+5) = (2, 3, 5)$$

## Question 2

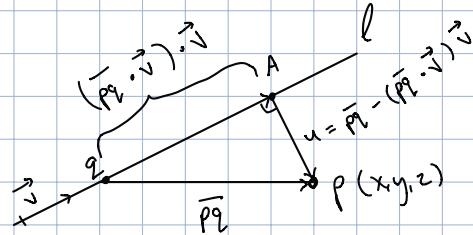

a) Let  $\ell(t) = q + vt$  be the parametric representation of a line, where  $v$  is a unit norm vector and  $q$  is a point on the line. Find the projection of a point

$p = (x, y, z)$  on the line  $\ell(t)$

$$\rightarrow \text{mark } q = (x_q, y_q, z_q)$$

$$\Rightarrow \vec{pq} = (x, y, z) - (x_q, y_q, z_q)$$

$$\vec{pq} = (x - x_q, y - y_q, z - z_q)$$

$\rightarrow$  let mark  $A$  the point on the line that most close to  $p$  and the vector  $\vec{u}$  is  $p - A \Rightarrow A = p - \vec{u}$  and  $A$  is the projection.

$$\Rightarrow \vec{u} = \vec{pq} - (\vec{pq} \cdot \vec{v}) \cdot \vec{v} = (x - x_q, y - y_q, z - z_q) - ((x - x_q, y - y_q, z - z_q) \cdot \vec{v}) \cdot \vec{v}$$

$$= (x - x_q, y - y_q, z - z_q) - \underbrace{((x - x_q)v_x + (y - y_q)v_y + (z - z_q)v_z)}_{\text{mark this as } \lambda} \cdot (v_x, v_y, v_z)$$

mark this as  $\lambda$

$$= (x - x_q - \lambda v_x, y - y_q - \lambda v_y, z - z_q - \lambda v_z)$$

$$\Rightarrow A = p - \vec{u} = (x, y, z) - (x - x_q - \lambda v_x, y - y_q - \lambda v_y, z - z_q - \lambda v_z)$$

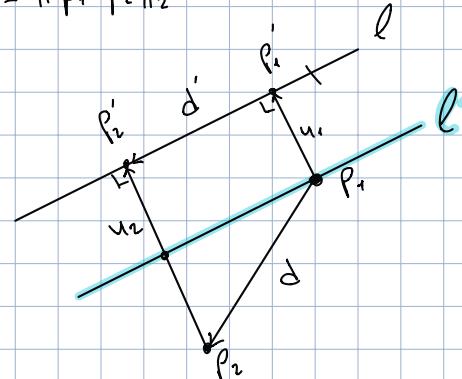

$$A = (x_q + \lambda v_x, y_q + \lambda v_y, z_q + \lambda v_z)$$

b) Let  $p_1$  and  $p_2$  be two points and let  $p'_1$  and  $p'_2$  be their projection on the line  $\ell$  respectively. Prove that  $\|p'_1 - p'_2\|_2 \leq \|p_1 - p_2\|_2$

$\rightarrow p'_1$  and  $p'_2$  are the projection points

$$\Rightarrow \text{the vectors } u_1 = \overrightarrow{p_1 p'_1} \text{ and } u_2 = \overrightarrow{p_2 p'_2}$$

are orthogonals to the line  $\ell$

let mark the distance between  $p'_1$  to  $p'_2$  as  $d'$

we can write  $\ell$  as follows:  $\ell = p'_1 + t \cdot (p'_2 - p'_1)$  for the vector  $(p'_2 - p'_1)$

let  $\ell'$  be a parallel line that passes through  $p_1$ ,  $\ell' = p_1 + t(p'_2 - p'_1)$

$\ell$  and  $\ell'$  have the same direction  $(p'_2 - p'_1)$ .

Since  $u_2 = (p'_2 - p_1)$  and  $u_1 = (p'_1 - p_1)$  is orthogonal to  $\ell$  their also

orthogonal to  $\ell'$ . Therefore the point  $A$  is the projection of  $p_2$  on line  $\ell'$ .

$p'_1, p'_1, p_1, A$  create a rectangle since there are 4

90° angles  $\Rightarrow$  the distance between  $|p'_1 - p'_2| = d'$  is equal

to the distance  $|p_1 - A| = d'$ .

So we get a 90° triangle  $p_1, A, p_2$

$$\text{from pythagoras } \Rightarrow \|p_1 - A\|^2 + \|p_2 - A\|^2 = \|p_1 - p_2\|^2$$

$$\Rightarrow \|p'_1 - p'_2\|^2 + \|p_2 - A\|^2 = \|p_1 - p_2\|^2$$

$$\text{since } \|p_2 - A\|^2 \text{ is a distance that } \geq 0 \Rightarrow \|p'_1 - p'_2\|^2 \leq \|p_1 - p_2\|^2$$

we can take out the root  $\Rightarrow \|p'_1 - p'_2\| \leq \|p_1 - p_2\|$

c) Can the argument in section (b) be extended to 2D planes?

Meaning, let  $p_1$  and  $p_2$  be two points and let  $p'_1$  and  $p'_2$  be their projections

on the 2D plane  $\Pi$ . Prove or Disprove that  $\|p'_1 - p'_2\| \leq \|p_1 - p_2\|$  for any

two points  $p_1, p_2$ . You may assume the plane  $\Pi$  is given by the unit normal

$n$  and a point  $q$ .

$\rightarrow$  Yes the argument can be extended to 2D planes and we can prove with similar way as we did in (b).

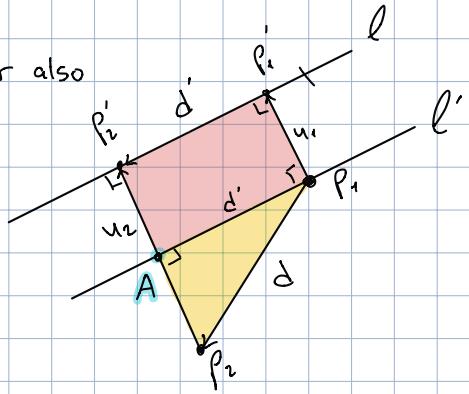

Define the plane  $\Pi: p'_1 + t \cdot \vec{v} + s \cdot \vec{u}$  for  $\vec{v}$  and  $\vec{u}$  some two vectors

on the plane. We can define a parallel plane of  $\Pi$  that passes

through  $p_1 \rightarrow \Pi': p_1 + t \vec{v} + s \vec{u}$  (we can use the same  $\vec{v}$  and  $\vec{u}$  because

the planes  $\Pi$  and  $\Pi'$  are parallel).

let mark the orthogonals vector  $(p'_1 - p_1) = h_1$  and  $(p'_1 - p_2) = n_2$

furthermore we know that  $p_2$  has a projection point on  $\pi'$  also with the same orthogonal vector  $n_2$  and a scalar  $c \rightarrow c \cdot n_2$

let mark this projection as  $A$ .

In the same way as in section (b) we

get a rectangle  $A, p_1, p_1', p_2'$

therefore the distance  $\|p_1' - p_2'\|$

is equal to  $\|A - p_1\|$

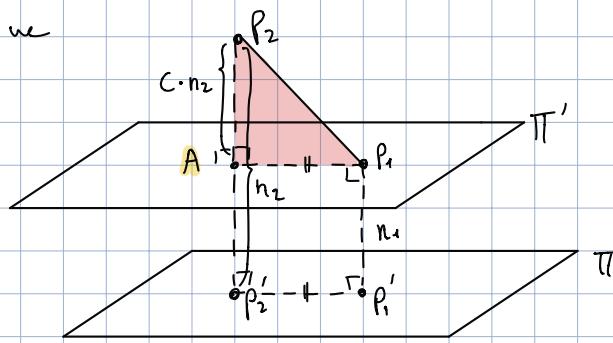

and we get a  $90^\circ$  triangle of  $A, p_2, p_1$

and according to pythagoras:

$$\|A - p_1\|^2 + \|A - p_2\|^2 = \|p_1 - p_2\|^2 \Rightarrow \|p_1' - p_2'\|^2 + \|A - p_2\|^2 = \|p_1 - p_2\|^2$$

$$\Rightarrow \|A - p_2\| \geq 0 \Rightarrow \|p_1' - p_2'\|^2 \leq \|p_1 - p_2\|^2 \Rightarrow \|p_1' - p_2'\| \leq \|p_1 - p_2\|$$

root out

### Question 3

A tetrahedral is given by the points:

$$P_0 = (2, -1, 0), P_1 = (2, 1, 0), P_2 = (-1, 1, 0), P_3 = (1, 0, 4)$$

a) Determine the unit normal (facing outside) of the triangles faces of the tetrahedron.

→ let mark the 4 faces as  $f_1, f_2, f_3$  and  $f_4$

- |                            |   |
|----------------------------|---|
| $f_1$ contains the vectors | $v_1 = P_2 - P_0$ and $u_1 = P_3 - P_0$ |
| $f_2$ contains the vectors | $v_2 = P_2 - P_1$ and $u_2 = P_3 - P_1$ |
| $f_3$ contains the vectors | $v_3 = P_3 - P_0$ and $u_3 = P_3 - P_1$ |
| $f_4$ contains the vectors | $v_4 = P_2 - P_0$ and $u_4 = P_2 - P_1$ |

$$v_1 = (-1, 1, 0) - (2, -1, 0) = (-3, 2, 0) \quad u_1 = (1, 0, 4) - (2, -1, 0) = (-1, 1, 4)$$

$$n_1 = v_1 \times u_1 = \begin{pmatrix} -3 \\ 2 \\ 0 \end{pmatrix} \times \begin{pmatrix} -1 \\ 1 \\ 4 \end{pmatrix} = \begin{pmatrix} 2 \cdot 4 - 0 \cdot 1 \\ 0 \cdot (-1) - (-3) \cdot 4 \\ -3 \cdot 1 - 2 \cdot (-1) \end{pmatrix} = \begin{pmatrix} 8 \\ 12 \\ -1 \end{pmatrix}$$

$$\hat{n}_1 = \frac{1}{\sqrt{8^2 + 12^2 + (-1)^2}} \cdot (8, 12, -1) = \frac{1}{\sqrt{209}} (8, 12, -1) \xrightarrow{\downarrow} \frac{1}{\sqrt{209}} (-8, -12, 1)$$

for facing outside

$$v_2 = (-1, 1, 0) - (2, 1, 0) = (-3, 0, 0) \quad u_2 = (1, 0, 4) - (2, 1, 0) = (-1, -1, 4)$$

$$n_2 = \begin{pmatrix} -3 \\ 0 \\ 0 \end{pmatrix} \times \begin{pmatrix} -1 \\ -1 \\ 4 \end{pmatrix} = \begin{pmatrix} 0 \cdot 4 - 0 \cdot (-1) \\ 0 \cdot (-1) - (-3) \cdot 4 \\ -3 \cdot (-1) - 0 \cdot (-1) \end{pmatrix} = \begin{pmatrix} 0 \\ 12 \\ 3 \end{pmatrix}$$

$$\hat{n}_2 = \frac{1}{\sqrt{0^2 + 12^2 + 3^2}} (0, 12, 3) = \frac{1}{\sqrt{153}} (0, 12, 3)$$

$$v_3 = (1, 0, 4) - (2, -1, 0) = u_1 = (-1, 1, 4) \quad u_3 = P_3 - P_1 = u_2 = (-1, -1, 4)$$

$$n_3 = \begin{pmatrix} -1 \\ 1 \\ -1 \end{pmatrix} \times \begin{pmatrix} -1 \\ -1 \\ 4 \end{pmatrix} = \begin{pmatrix} 4 - (-4) \\ -4 - (-4) \\ 1 - (-1) \end{pmatrix} = \begin{pmatrix} 8 \\ 0 \\ 2 \end{pmatrix}$$

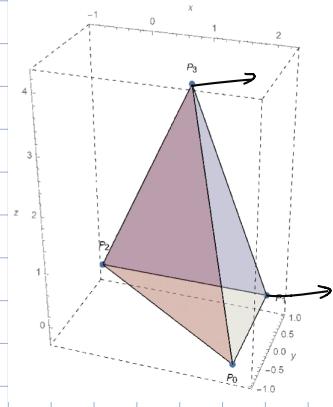

$$\hat{n}_3 = \frac{1}{\sqrt{8^2 + 0^2 + 2^2}} \cdot (8, 0, 2) = \frac{1}{\sqrt{68}} (8, 0, 2)$$

$$v_4 = v_1 = (-3, 2, 0) \quad u_4 = v_2 = (-3, 0, 0)$$

$$n_4 = \begin{pmatrix} -3 \\ 2 \\ 0 \end{pmatrix} \times \begin{pmatrix} -3 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 - 0 \\ 0 - 0 \\ 0 - 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\hat{n}_4 = \frac{1}{\sqrt{0^2 + 0^2 + 6^2}} (0, 0, 6) = \frac{1}{6} (0, 0, 6) \xrightarrow{\downarrow} \frac{1}{6} (0, 0, -6)$$

for facing outside

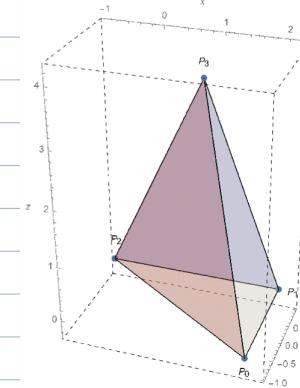

b) Calculate the implicit equation of the planes that contain the tetrahedron's faces

→ let mark the 4 faces as  $f_1, f_2, f_3$  and  $f_4$

- $f_1$  contains the vectors  $v_1 = p_2 - p_0$  and  $u_1 = p_3 - p_0$
- $f_2$  contains the vectors  $v_2 = p_2 - p_1$  and  $u_2 = p_3 - p_1$
- $f_3$  contains the vectors  $v_3 = p_3 - p_0$  and  $u_3 = p_3 - p_1$
- $f_4$  contains the vectors  $v_4 = p_2 - p_0$  and  $u_4 = p_2 - p_1$

$$v_1 = (-1, 1, 0) - (2, -1, 0) = (-3, 2, 0) \quad u_1 = (1, 0, 4) - (2, -1, 0) = (-1, 1, 4)$$

$$n_1 = v_1 \times u_1 = \begin{pmatrix} -3 \\ 2 \\ 0 \end{pmatrix} \times \begin{pmatrix} -1 \\ 1 \\ 4 \end{pmatrix} = \begin{pmatrix} 2 \cdot 4 - 0 \cdot (-1) \\ 0 \cdot (-1) - (-3) \cdot 4 \\ -3 \cdot 1 - 2 \cdot (-1) \end{pmatrix} = \begin{pmatrix} 8 \\ 12 \\ -1 \end{pmatrix}$$

$$\Rightarrow f_1: 8x + 12y - z + d = 0 \rightarrow f_1(p_0) = 8 \cdot 2 + 12 \cdot (-1) - 0 + d = 0$$

$$16 - 12 = -d \rightarrow d = -4$$

$$f_1: 8x + 12y - z - 4 = 0 \quad (\cdot (-1)) \rightarrow f_1: -8x - 12y + z + 4 = 0$$

$$v_2 = (-1, 1, 0) - (2, 1, 0) = (-3, 0, 0) \quad u_2 = (1, 0, 4) - (2, 1, 0) = (-1, -1, 4)$$

$$n_2 = \begin{pmatrix} -3 \\ 0 \\ 0 \end{pmatrix} \times \begin{pmatrix} -1 \\ -1 \\ 4 \end{pmatrix} = \begin{pmatrix} 0 \cdot 4 - 0 \cdot (-1) \\ 0 \cdot (-1) - (-3) \cdot 4 \\ -3 \cdot (-1) - 0 \cdot (-1) \end{pmatrix} = \begin{pmatrix} 0 \\ 12 \\ 3 \end{pmatrix}$$

$$\Rightarrow f_2: 0 \cdot x + 12y + 3z + d = 0 \rightarrow f_2(p_1) = 0 + 12 \cdot 1 + 0 + d = 0 \rightarrow d = -12$$

$$f_2: 0 + 12y + 3z - 12 = 0$$

$$v_3 = (1, 0, 4) - (2, -1, 0) = u_1 = (-1, 1, 4) \quad u_3 = p_3 - p_1 = u_2 = (-1, -1, 4)$$

$$n_3 = \begin{pmatrix} -1 \\ 1 \\ -1 \end{pmatrix} \times \begin{pmatrix} -1 \\ -1 \\ 4 \end{pmatrix} = \begin{pmatrix} 4 - (-4) \\ -4 - (-4) \\ 1 - (-1) \end{pmatrix} = \begin{pmatrix} 8 \\ 0 \\ 2 \end{pmatrix} \Rightarrow f_3: 8 \cdot x + 0 \cdot y + 2z + d = 0 \quad f_3(p_1) = 8 \cdot 2 + 0 + 0 + d = 0$$

$$d = -16$$

$$f_3: 8x + 0 + 2z - 16 = 0$$

$$v_4 = v_1 = (-3, 2, 0) \quad u_4 = v_2 = (-3, 0, 0)$$

$$n_4 = \begin{pmatrix} -3 \\ 2 \\ 0 \end{pmatrix} \times \begin{pmatrix} -3 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 - 0 \\ 0 - 0 \\ 0 - (-6) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 6 \end{pmatrix} \Rightarrow f_4: 0 \cdot x + 0 \cdot y + 6z + d = 0 \quad f_4(p_2) = 0 + 0 + 6 \cdot 0 + d = 0$$

$$d = 0$$

$$f_4: 0 + 0 + 6z + 0 = 0 \quad (\cdot (-1))$$

$$f_4: -6z = 0$$

c) Explain in-detail how to determine if a point  $p = (x, y, z)$  is inside the tetrahedral.

→ To determine if a point  $p = (x, y, z)$  is inside the tetrahedral we need to put p's values in each of the equations we got in section (b). If at all the equations we received a negative value it means that the point p is in the tetrahedral.

If at one or more equation we get a positive value it is not in the tetrahedral.

d) A point  $p = (x, y, z)$  lies inside the tetrahedral. Determine the distance of the point  $p = (x, y, z)$  from the tetrahedral surface.

→ We need to find the projection point of p on each of the faces of the tetrahedral. Then the size of the vector between p and each projection will be the distance from each face respectively.

for  $f_1$  we will take  $p_2$  that on this face and

define the vector  $(p - p_2) = (x+1, y-1, z)$ . Now we

project this vector on  $n_1 \rightarrow ((x+1, y-1, z) \cdot \vec{n}_1) \vec{n}_1$

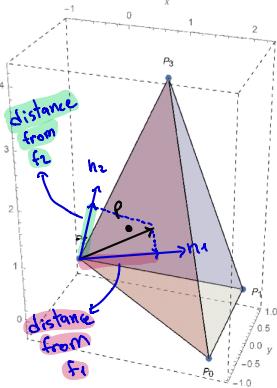

$$= \frac{-8(x+1) - 12(y-1) + 2}{\sqrt{209}} \rightarrow \left| \frac{-8(x+1) - 12(y-1) + 2}{\sqrt{209}} (-8, -12, 1) \right|$$

and this is the distance we need to take off p to get to the projection of p on  $f_1 \Rightarrow$  this is exactly the **distance from  $f_1$** .

for  $f_2$  we also can take  $p_2 \rightarrow (x+1, y-1, z)$  and we need to project

$$\text{this vector on } n_2 \rightarrow ((x+1, y-1, z) \cdot \vec{n}_2) \vec{n}_2 = \frac{12(y-1) + 3z}{\sqrt{153}} (0, 12, 3)$$

$$\rightarrow \left| \frac{12(y-1) + 3z}{\sqrt{153}} (0, 12, 3) \right| \text{ as the same way this the } \text{distance from } f_2.$$

for  $f_3$  we can take the point  $p$  which lies on this face. Define the vector  $(p - p_1) = (x-2, y-1, z)$  and the projection of this vector on  $n_3 \rightarrow ((x-2, y-1, z) \cdot \vec{n}_3) n_3 = \frac{8(x-2) + 2z}{\sqrt{68}} (8, 0, 2) \rightarrow \left| \frac{8(x-2) + 2z}{\sqrt{68}} (8, 0, 2) \right|$

and this the distance from  $f_3$ .

for  $f_4$  we also can take  $p$  so we get the vector  $(x-2, y-1, z)$  and need to project it on  $n_4 \rightarrow \frac{-6z}{6} (0, 0, -6) \rightarrow \left| \frac{-6z}{6} (0, 0, -6) \right|$

and this the distance from  $f_4$ .
